

Extensibility

Extensibility allows to programmatically extend StresStimulus functionality and behavior. You can write your own custom logic that can access internal test object model (TOM), generate test parameters, modify HTTP requests and responses and create other customizations.

Extensibility allows to:

- create scriptable variables that can be used to create a custom request parameter of any complexity;
- create external components that can be used to modify StresStimulus event handling and change requests and responses based on the test context information.
